Summary	3-5
Abbreviations	6
Map of Soil Monitoring Sites	7
Attachment A: Dioxin/Furan TEQ results in soil and ash	8-12
Attachment B: PCB results in soil and ash	13-17
Attachment C: Metal results in soil	18-28
Attachment C-1: Comparison levels for metals in soil	29-30
Attachment D: Metal results in ash	31-37

Summary Statement:

In the monitoring conducted to date, no relationship has been established between the operation of the Waste-to-Energy Facility and any significant increased levels of constituents in the environment.

Introduction

The Onondaga County Health Department initiated a Waste-to-Energy Facility monitoring program in 1994, the year prior to the facility being placed into operation. In 2003, the monitoring program for air, soil and ash was reevaluated, and a more effective and efficient program was developed and implemented starting in 2004. As an alternative to offsite air monitoring, direct interaction was established with the Onondaga County Resource Recovery Agency (OCCRA) and the New York State Department of Environmental Conservation (DEC) in providing stack monitoring results and improved assurance on reporting of adverse events and equipment failures. This allows for evaluation of short-term changes in the Waste-to-Energy Facility emissions, an effective alternative to the previous limited scope offsite air monitoring conducted over a nine year period.

Long-term deposition impacts continue to be evaluated by soil and ash monitoring. All soil samples are analyzed for metals twice a year. Several changes related to organics testing have been implemented based on the low levels detected in the monitoring conducted to date, and the fact that there is no evidence of a trend or levels associated with health risks. Starting in 2009, half of the soil sampling sites were analyzed for organics each year; therefore each site is sampled biennially. The monitoring program has the flexibility of testing a site again in the following year should an elevated level of any organic constituent be detected. The four soil ash route sites have been eliminated from the program. Historically, these sites do not show any elevation of metals or organics indicating that ash transport in covered vehicles is not a significant environmental or health concern. Ash, directly from the Waste-to-Energy Facility continues to be analyzed for metals twice a year and organics once a year. Under present contracts, organic analysis is performed by Axys Analytical Services, LTD, and metal analysis is performed by Life Science Laboratories, Inc. The collection of soil is performed by Onondaga County Health Department, Division of Environmental Health staff, while collection of the ash is the responsibility of Covanta Energy System under New York State Department of Environmental Conservation protocols.

During 2017, the Waste-to-Energy facility processed 330,223 tons of waste which is up slightly from last year's value of 327,869 tons.

Air Monitoring

During 2017, the department interacted directly with OCCRA and DEC in review of the stack monitoring results and reporting of adverse events and equipment failures by the facility operator, Covanta Energy. The department also reviewed both the monitoring conducted at the stack on a continuous basis and reported quarterly to DEC, as well as the

annual stack test that is performed by an independent contractor. At no time did the monitoring indicate constituents above levels of health concern. The annual stack test incorporates an extensive list of analytes that include metals and organics. All of the analytes were well below permit limits.

Soil and Ash Testing for Organics

Soil from six routine sites and one control site, collected in the spring of 2017, was analyzed for dioxins/furans (PCDD/PCDF), polychlorinated biphenyls (PCB's), and polycyclic aromatic hydrocarbons (PAH's). Ash, also collected in the spring of 2017, was analyzed for the same constituents.

Organic sample results are compared to published background data and U.S. Department of Health and Human Services, Agency for Toxic Substances and Disease Registry (ATSDR) Toxicological Profiles, EPA Preliminary Remediation Goals, and NYSDEC Soil Cleanup Objectives. In general, little change in levels of these compounds has been observed from background through the present organic screening period. The levels of organics in the ash were similar to reports for ash identified by other investigators and reported in published literature.

Each form of dioxin/furan has associated with it a toxic equivalency factor that is used to calculate a total toxic equivalency (TEQ) for each sample. **Attachment A** shows the historical dioxin/furan TEQ values for soil sites and ash samples. All levels remain well below the ATSDR and EPA action levels and there is no indication of a trend. For ash, dioxin/furan total TEQ remain fairly consistent. Ash is not homogeneous and an inconsistent result occurs occasionally. The results are similar to those reported by other investigators.

Attachment B shows the historical PCB values for soil sites and ash samples. All levels remain below the ATSDR and EPA action levels and there is no indication of a trend.

Soil and Ash Testing for Metals

Soil from the fourteen soil sites and ash were analyzed for ten different metals twice during the year (Spring and Fall). The metal results are issued in two different reports, one for soils and one for ash.

In 2011, due to improvements in the contract laboratory's equipment, the detection limits for beryllium, cadmium, and selenium have been lowered. Therefore there are detectable levels of these metals in many of the samples as compared to previous years.

Metal results are compared to background levels, published national averages for urban areas and a statewide rural soil survey. Soil and ash are not homogeneous and can contain materials that can account for an occasional inconsistent result. Hence, a single elevated or depressed value will not be assumed to be indicative of a change at a specific site. Rather, the pattern of values for that specific element must demonstrate a statistically significant difference, which may be indicative of a real environmental change. In general, the metal results for 2017 fall within the expected range of values for urban areas and demonstrate no significant variation from background levels.

Attachment C shows the historical levels for the ten metals at the routine and control soil sites. Due to the volume of data, the mean (average) of all routine sites and all control sites for each year is presented. The complete report includes all of the data for each site. Attachment C-1 provides data on New York State Department of Environmental Conservation Soil Cleanup Objectives, a New York State rural soil survey, and USEPA soil screening levels for metals in residential soil.

Attachment D shows the historical levels of the ten metals in ash.

Summary and Conclusions

In general, the organic and metal results for this monitoring period are within the expected range for urban environments and are below any levels associated with health risk. Any fluctuations in sample results appear to be a reflection of the low levels detected, expected variation as a result of sample collection, preparation, and laboratory procedures, or possible variable levels due to past activities at a site. All levels remain below those associated with health concerns. The results should be viewed in the context of an ongoing program of environmental monitoring performed by the Onondaga County Health Department as a part of its overall Waste-to-Energy Facility Monitoring Program. In the monitoring conducted to date, no relationship has been established between the operation of the Waste-to-Energy Facility and any significant increased levels of constituents in the environment.

The following are the detailed Waste-to-Energy Facility Monitoring Program reports that have been issued on the 2016 soil and ash testing:

2017 Screening Summary for Organic Constituents

2017 Soil Metals Analysis Summary

PCB results prior to 2000 were all less than detection limits. Starting in 2000 detection limits were lowered so that usable concentrations were available.

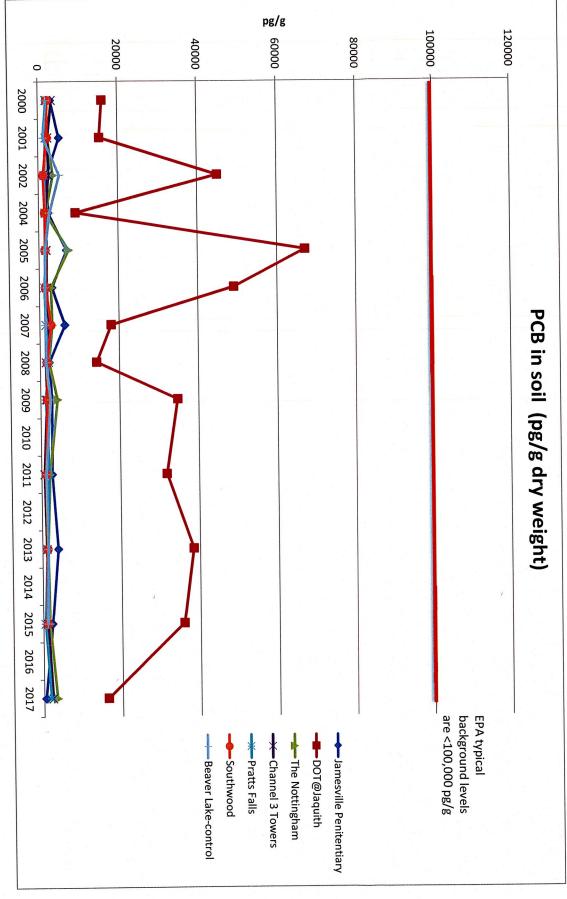

Note: For reference purposes, the ATSDR indicates that typical mean PCB concentrations in background soil are less than 100,000 pg/g

Denotes Control Sites
 Site no longer sampled due to program re-evaluation
 Site not sampled this year. Sites are sampled every other year.

Comparison Levels for Metals in Soil

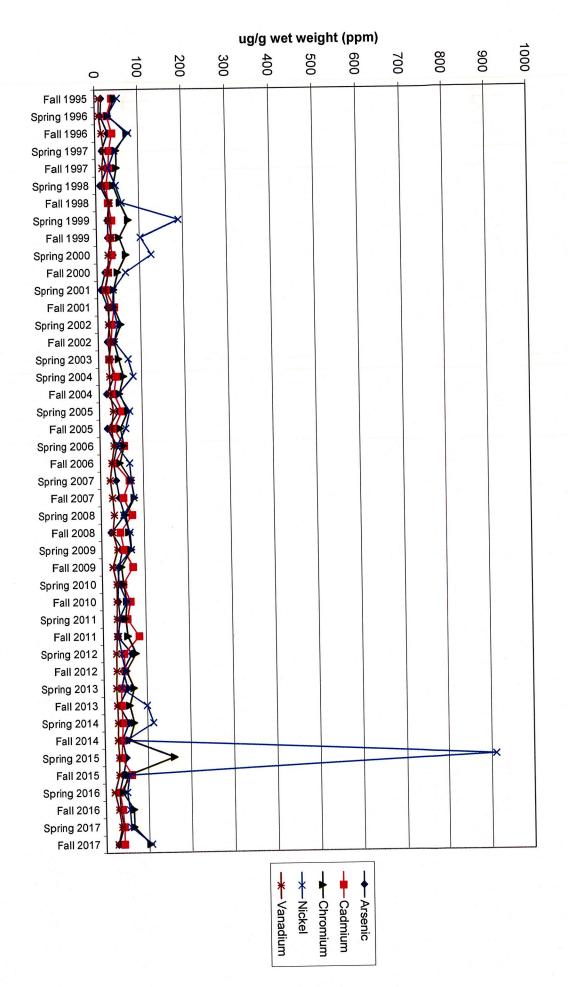

Metal	NYS SCO's for restricted use residential (ppm)	Rural Soil Survey (ppm)	USEPA Soil Screening levels for residential (ppm)
Arsenic	16 (0.21)	16	0.39
Beryllium	14	1.2	160
Cadmium	2.5 (0.86)	2.5	70
Chromium	36	30	280
Lead	400	133	400
Mercury	0.81	0.3	6.7
Nickel	140	29.5	1600
Selenium	36	4	390
Vanadium	NA	38	390
Zinc	2,200	180	23,000

New York State Department of Environmental Conservation Soil Cleanup Objectives. The Health Based SCO's were calculated considering all exposure pathways: ingestion, inhalation, dermal, carcinogenic (1 in a million cancer risk), and non-carcinogenic (using risk reference doses). The final health based SCO is based on the most conservative pathway calculation. In some cases the SCO has been modified to match background if the rural background levels for NYS are above the calculated SCO (the health based SCO is in parenthesis). Restricted use means no livestock or animal product consumption.

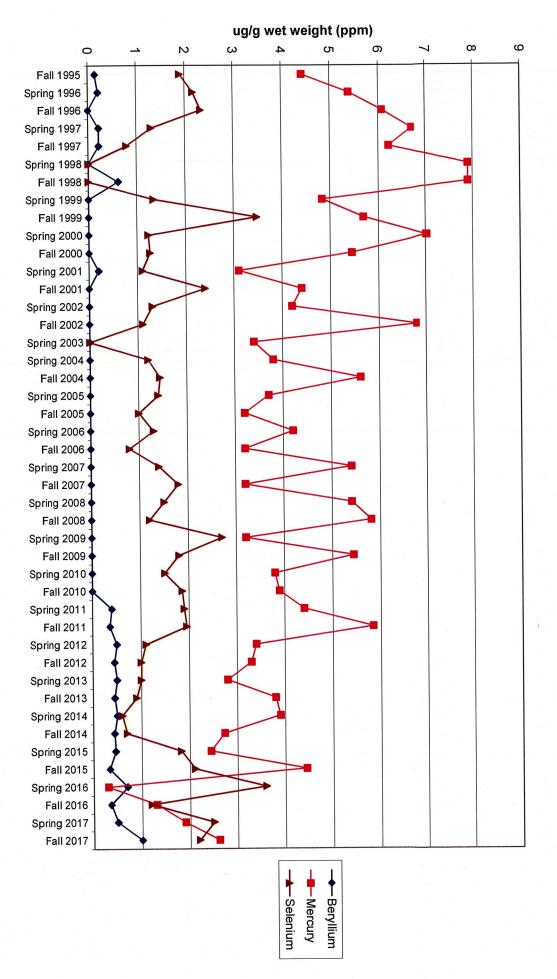

NYS Statewide Rural Surface Soil Survey (2005)-determined concentration ranges for 170 commonly assessed analytes in discrete surface soil samples collected at randomly selected rural NYS properties.

USEPA Soil Screening Levels for residential—Values were calculated based on the ingestion-dermal exposure pathway for residential soils. These screening levels are not action levels or clean up levels, they are a tool for further evaluation.
